

Exercise 8

What is a collision domain: a collision domain is a shared physical medium that multiple end devices use, and therefore signals can collide.

Network devices that divide collision domains: Switch, Bridge, Router. They are put between other small networks to stop the collide

Which network devices do not divide collision domains? Name them all: Hub, Repeater.

What does broadcast domain mean: A broadcast domain is a part of a network where a broadcast frame (e.g. ARP request) is forwarded to all devices in that domain

What does block broadcast domain mean: block broadcast traffic means that the device does not redirect the traffic (packets) to all other connected devices.

Name the network devices which divide broadcast domains: Router, Layer-3 Switch. They are put between small networks to stop the broadcasting

Sketch all collision domains (in dotted lines) and all broadcast domains (in grey lines) of the given network diagram:

Collision domain: Hub, Repeater

Broadcast domain: hub, repeater, L2 switch, bridge.
